

SC-WBD — four trained whole-brain models, and the next one

Every brain is the same drawing: 414 parcels of one person's brain at their real coordinates, over the strongest 900 white-matter tracts.

Height $\propto \log_{10}(\text{parameters}) - 5$, offset so the series is legible; areas are not parameter ratios. Held-out NLL is nats per channel per sample on participant-disjoint EEG, lower is better. 001 and 002 were scored in different units from their baselines and read ~ 0.6 nats low; correcting moves both further behind, so the verdicts stand. 003 and 004 used different split policies.
